QIU

### Problem Statement

- Signal occurs during contraction where there are **synchronous activities in the muscles**.
- This **signal can be obtained** by EMG, US and TI.
- Research on correlation between any of these three modalities **were limited**.
- A mechanism is needed for the signal acquisition when we **combine all the 3 terms** for muscle strength measurement.

## Objectives

QIU

- To understand the basic concepts of EMG, ultrasound and thermal imaging for the muscle activity signal acquisition.
- To investigate the correlation of EMG, ultrasound and thermal imaging for the muscle condition.
- To introduce a new system that integrates these modalities.

### Critical Analysis (Cont.)

QIU

## Methodology

QIU

- Conducted the experiment on 8 male students with strong biceps muscles.

### EMG

Equipment:  
16 Channel Trigno Wireless EMG Set (DELSYS)

Software:  
EMGWorks Software 4.07

Parameters:  
Amplitude Analysis  
MAV  
RMS

### Thermal Imaging

Equipment:  
Fluke T132 9Hz Thermal Imager

Software:  
Fluke SmartView 3.1 Software

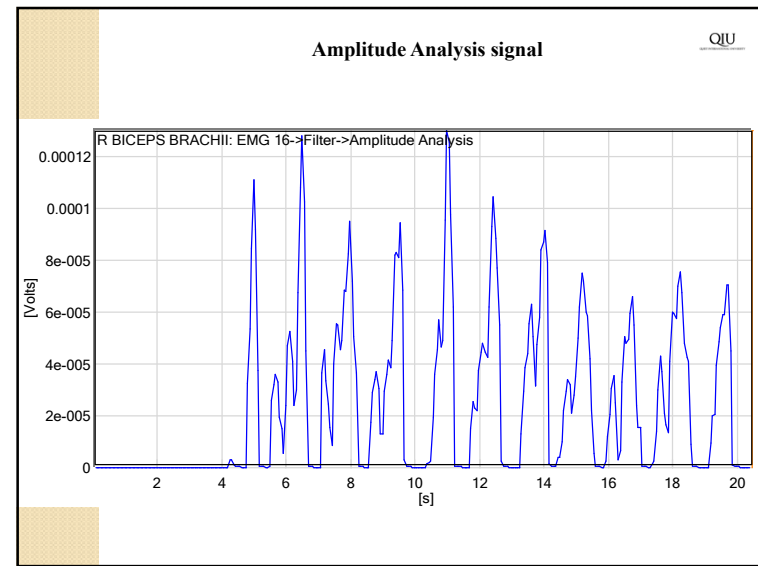

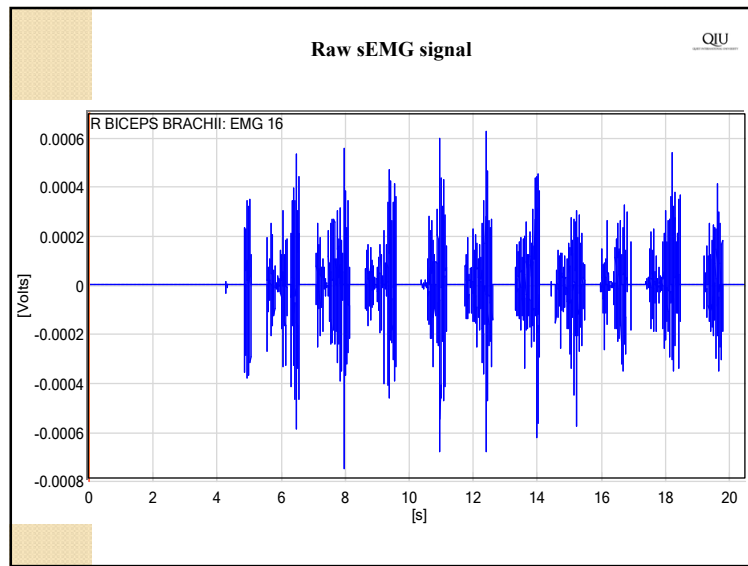

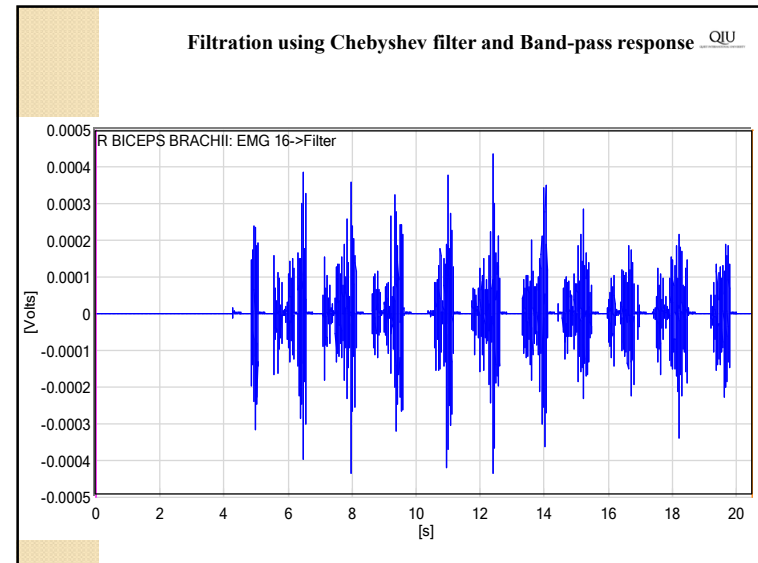

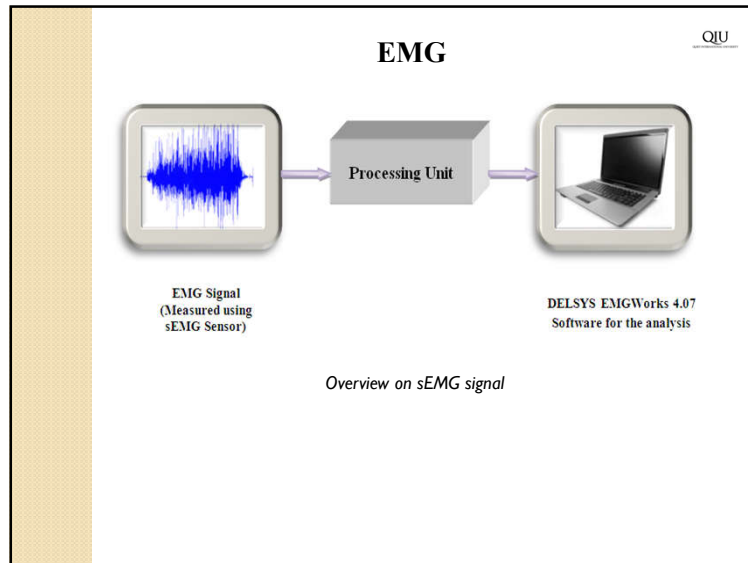

Parameter:  
Temperature (°F)

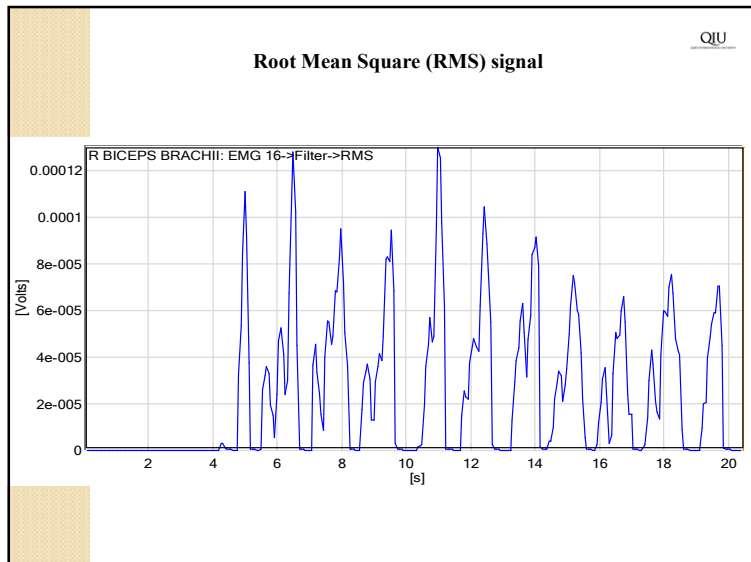

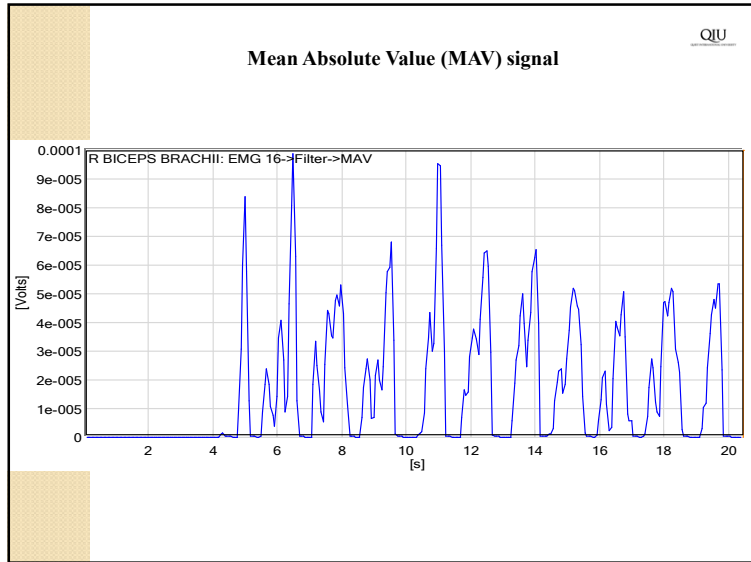

### Ultrasound

Equipment:  
Ultrasound Machine GE Logiq E BT 2011

Software:  
MATLAB

Parameter:  
Muscle Compression

| Subject | Contraction | Without Load | With Load |
|---------|-------------|--------------|-----------|
| 2       | Before      |              |           |
|         | After       |              |           |

### Ultrasound

QIU

Image of the estimation on how the ultrasound image is acquired

Profile of Contraction Change (CC) of the Biceps Brachii Muscle

$$CC = AB_{max} - AB_{min}$$

### Per unit

QIU

- The Per Unit value is used to quantify the parameters and is a method of expressing quantities (parameters) as a **proportion of pre-defined base quantities**.
- Generally, the PU is the **ratio of the original value to its base value** which will then results in a **dimensionless** or no unit values.
- Base value in this case study is the measurement's highest value for each parameter that has been proposed.

$$\text{Per Unit} = \frac{\text{Present Value}}{\text{Base Value}}$$

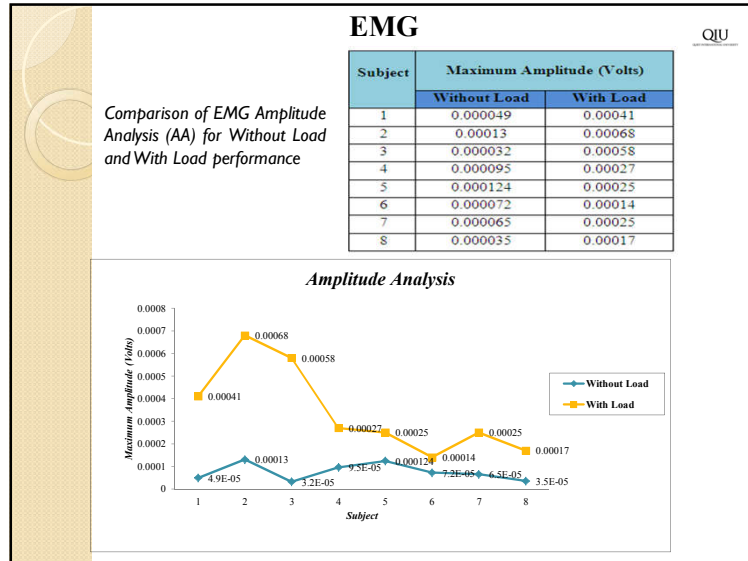

- The **analysis can be simplified** by using the PU system and therefore **the relative magnitude** of all similar quantities **can be directly compared**.

| Subject | Contraction | Without Load | With Load |
|---------|-------------|--------------|-----------|
| 2       | Before      |              |           |
|         | After       |              |           |

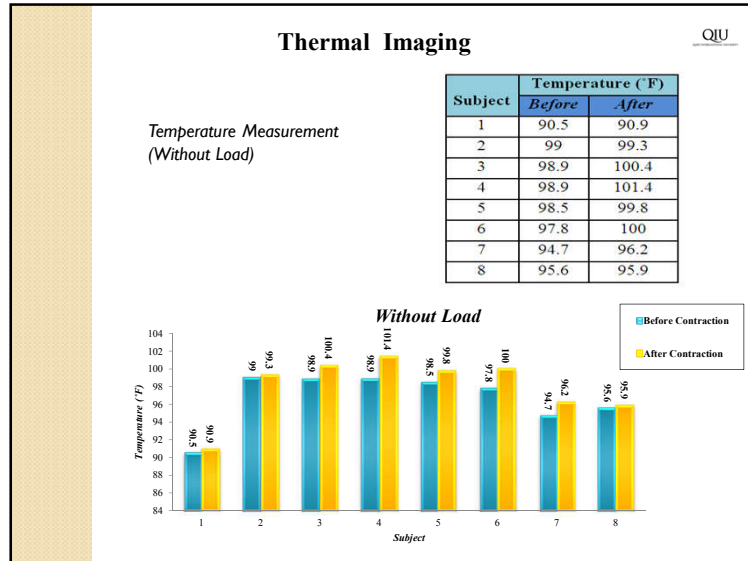

QIU

## ANALYSIS RESULTS

QIU

- QIU
- The **increase of amplitude** in the signal of with load condition is consistent for all the subjects.
  - That means all eight subjects **achieved higher amplitude** after the muscle contraction **using load**.
  - It reveals the **relationship between the muscle contractibility,  $M_c$  and the amplitude** where the function is given by:
 
$$M_c = f(E_A)$$
  - The equation demonstrates that the **muscle contractibility is proportional to the amplitude** of the EMG.
  - The result of **MAV and RMS** also shows the increase in amplitude when the subject performs contraction using load of 10lb dumbbell.

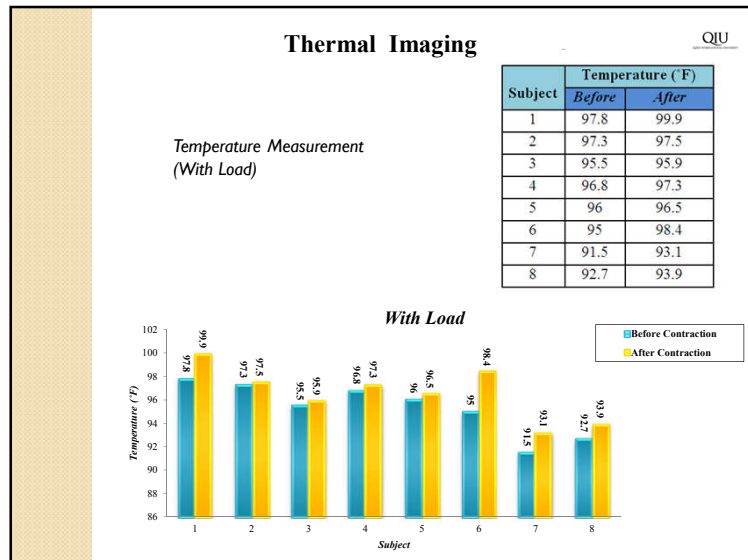

QIU

- The results of the thermal imaging showed a **good relationship** between the muscle contractibility,  $Mc$  and the **temperature change** of the both without load and with load performance.

$$Mc = f(T_i)$$

- The function above shows that the **increase in temperature after the contraction activity** is **proportional** to the muscle contractibility,  $Mc$ .
- The higher the value of the subjects' **temperature, the muscle contraction increases.**

### Ultrasound

QIU

| Subject | Compression Length (cm) |       |                        |           |       |                        |
|---------|-------------------------|-------|------------------------|-----------|-------|------------------------|
|         | Without Load            |       |                        | With Load |       |                        |

| 4       | 4                       | 1.5   | 2.5                    | 2.5       | 2     | 2                      |
| 5       | 3.5                     | 2.5   | 1                      | 2.8       | 2.3   | 0.5                    |
| 6       | 3.5                     | 2.5   | 1                      | 2.5       | 2     | 0.5                    |
| 7       | 4.1                     | 3.5   | 0.6                    | 2         | 1.5   | 0.5                    |
| 8       | 3.5                     | 2.5   | 1                      | 1.8       | 1     | 0.8                    |

*Difference between the Muscle Thickness for the Without Load and With Load Conditions*

QIU

- The results demonstrated that the Contraction Change (CC) of **without load** condition is **higher** than the CC of **with load** condition.
- It means that the **compression of muscle using load is higher** as compared to the muscle compression without using load.
- The **biceps brachii were compressed more** when the subject was applying too much of pressure on the muscle area.
- This shows a **proportional relationship** between the **muscle thickness and the muscle contractibility** which is given by the equation below:
 
$$Mc = f\left(\frac{1}{h}\right)$$
- Where **h is the contraction change (CC)** of the muscle that reveals the contraction change of the with load activity is higher than the contraction change of the without load activity.

### Correlation between EMG and Ultrasound (US)

QIU

| Subject | Without Load       |                  |            | Subject | With Load          |                  |            |

Per Unit Values for the TI and EMG (Without Load)      Per Unit Values for the TI and EMG (With Load)

- Two modalities were compared: With Load and Without Load.
- Proportional correlation.
- Both the modalities showed an increased during the muscle contraction using load.
- The results showed a good performance.

Per Unit Values for the TI and US (Without Load)      Per Unit Values for the TI and US (With Load)

**Conclusion** QJU

- A significant and relevant **proportional relationship** between the EMG, TI and US was identified.
- It can be stated that EMG, TI and US is a promising option to **quantitatively estimate the muscle strength**.
- All the **three modalities were strongly correlated** with its muscle strength level (MSL).
- The results of the correlation shows that there is increase in **amplitude for EMG**; **increase in temperature** for TI and also **increase in muscle compression** for the US when the muscle is contracted **using load**.

- The results and analysis of the correlation rev. QJU that it showed a very **good relationship** (performance) on the muscle contractibility.
- A **mathematical function** is generated from the correlation of the three modalities.
- The function is given by the equation below;
 
$$\text{Muscle Contractibility, } M_c \propto f\left(E_A, T_I, \frac{1}{h}\right)$$
- It is proven that the contractibility of muscle is **proportional** to the **increase of temperature** of thermal imaging, **amplitude for the EMG**, and **muscle compression change for the ultrasound when a force (load)** is applied to the muscle during its contraction.

**Future Works / Recommendation** QJU

- ❖ Involve a group of large number of subjects.
- ❖ Multiple load variables.
- ❖ Other anatomical parts of human body.
- ❖ Muscle fatigue measurement.
- ❖ Can be applied in Injury identification/mapping in the future.
